ABSTRACT

The numerical solution of Huxley equation by the use of two finite difference methods is done. The first one is the explicit scheme and the second one is the Crank-Nicholson scheme. The comparison between the two methods showed that the explicit scheme is easier and has faster convergence while the Crank-Nicholson scheme is more accurate. In addition, the stability analysis using Fourier (von Neumann) method of two schemes is investigated. The resulting analysis showed that the first scheme is conditionally stable if 
\[
\begin{align*}
\Delta t \leq \frac{2(\Delta x)^2}{4 - a\beta(\Delta x)^2} \\
2 - a\beta\Delta x \leq \frac{4}{\Delta r}
\end{align*}
\]
and the second scheme is unconditionally stable.

Keywords: Finite Difference Methods, Explicit Scheme, Crank-Nicholson, Huxley Equation, Stability Analysis.

الحل العددي وتحليل الاستقرار لمعادلة Huxley

الملخص

تم حل معادلة Huxley باستخدام طريقتين من طرق الفروقات المنتهية: الأولى هي Crank-Nicholson حيث تم عمل مقارنة بين نتائج كلاً من الطرقتين وقد تبين أن الطريقة الأولى هي الأسهل والأسرع قارياً في حين كانت الطرقتين الثانية هي Fourier von (Neumann) إذا تبين أن الطريقة الأولى مستقرة على نحو مشروط إذا كان 
\[
\begin{align*}
2 - a\beta\Delta x \leq \frac{4}{\Delta r} \\
\Delta t \leq \frac{2(\Delta x)^2}{4 - a\beta(\Delta x)^2}
\end{align*}
\]
مشروط.
1. Introduction

It is probably not an overstatement to say that almost all partial differential equations (PDEs) that arise in a practical setting are solved numerically on a computer. Since the development of high-speed computing devices, the numerical solution of PDEs has been in active state with the invention of new algorithms and the examination of the underlying theory. This is one of the most active areas in applied mathematics and it has a great impact on science and engineering because of the ease and efficiency it has shown in solving even the most complicated problems. The basic idea of the method of finite differences is to cast the continuous problem described by the PDE and auxiliary conditions into a discrete problem that can be solved by a computer in finitely many steps. The discretization is accomplished by restricting the problem to a set of discrete points. By systematic procedure, we then calculate the unknown function at those discrete points. Consequently, a finite difference technique yields a solution only at discrete points in the domain of interest rather than, as we expect for an analytical calculation, a formula or closed-form solution valid at all points of the domain [11]. Manoranjan et al [12] obtained estimates for the critical lengths of the domain at which bifurcation occurs in the cases $b = 0, a, 0 < a \leq 1/2$, and 1.

In this paper, the numerical solution of Huxley equation by using two finite difference methods and stability analysis of these two methods are analyzed.

2. The Mathematical Model

One of the famous non-linear reaction-diffusion equations is the generalized Burgers-Huxley (gBH) equation:

\[
\frac{\partial u}{\partial t} + \alpha u \frac{\partial u}{\partial x} - \beta \frac{\partial^2 u}{\partial x^2} = \beta \delta (1 - u^\delta) (u^\delta - a) \quad (1)
\]

\(\alpha \geq 0, \beta \geq 0, \delta > 0, \text{and } a \in (0, 1)\)

If we take \(\delta = 1, \alpha \neq 0, \text{and } \beta \neq 0\), equation (1) becomes the following Burgers-Huxley (BH) equation:

\[
\frac{\partial u}{\partial t} + \alpha u \frac{\partial u}{\partial x} - \frac{\partial^2 u}{\partial x^2} = \beta (1 - \delta) (u - a) \quad (2)
\]

Equation (2) shows a prototype model for describing the interaction mechanism, convection transport. When \(\beta = 0, \text{and } \delta = 1\), equation (1) is reduced to Burgers equation which describes the far field of wave propagation in nonlinear dissipative systems

\[
\frac{\partial u}{\partial t} + \alpha \frac{\partial u}{\partial x} - \frac{\partial^2 u}{\partial x^2} = 0 \quad (3)
\]

When \(\alpha = 0, \text{and } \delta = 1\), equation (1) is reduced to the Huxley equation which describes nerve pulse propagation in nerve fibers and wall motion in liquid crystal

\[
\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} = \beta (1 - \delta) (u - a) \quad (4)
\]

It is known that nonlinear diffusion equations (3) and (4) play important roles in nonlinear physics. They are of special significance for studying nonlinear phenomena [19]. Zeldovich and Frank-Kamenetsky formulated the equation (4) in 1938 as a model for flame front propagation and for this reason this equation sometimes named Zeldovich-Frank-Kamenetsky (ZF) equation, which has been extensively studied as a simple nerve model [1]. In 1952 Hodgkin and Huxley proposed their famous Hodgkin-Huxley model for nerve propagation. Because of the mathematical complexity of this model, it led to the introduction of the simpler Fitzhugh-Nagumo system. The simplified model of the Fitzhugh-Nagumo system is Huxley equation [18]. Because Huxley equation is a special case of Fitzhugh-Nagumo system, it is sometimes named Fitzhugh-Nagumo (FN) equation [5] or the reduced Nagumo equation or Nagumo equation [15]. In sixties, Fitzhugh used equation (4) as an approximate equation for the
description of dynamics of the giant axon. This equation was among the first models of excited media [8].

In this paper, we shall take the Huxley equation as a model problem [12]:

\[
\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} = \beta u(1-u)(u-a)
\]

\[x \in [-L, L], \ t \geq 0\]

\[u(x,0) = (b-H)x^2 + H, \ b \geq 0, \ H > 0\]

\[u(-L,t) = u(L,t) = b\]

For the purpose of numerical calculations, we shall take:

\[\beta = 1, \ a \in (0, 1), \ L = 1, \ 0 \leq b \leq 1, \ and \ 0 < H \leq 1, \ 0 \leq t \leq 3.\]

3. Derivation of the Explicit Scheme Formula of Huxley Equation [14] is

\[R = \{ (x,t): -L \leq x \leq L, 0 \leq t \leq c \}\]

Assume that the rectangle subdivided into \((n-1)\) by \((m-1)\) rectangles with sides \(\Delta x = h, \ \Delta t = k\).

Start at the bottom row, where \(t = t_1 = 0\), and the initial condition is [12]:

\[u(x_i, t_1) = f(x_i) = (b-H)x_i^2 + H, \ i = 2, 3, ..., n-1.\]

A method for computing the approximations to \(u(x, t)\) at grid points in successive rows will be developed

\[\{u(x_i, t_j): i = 2, 3, 4, ..., n-1\}, \ j = 2, 3, 4, ..., m\]

The difference formulas used for \(u_i(x,t)\) and \(u_{ix}(x,t)\) are:

\[u_i(x,t) = \frac{u(x,t+k) - u(x,t)}{k} + O(k)\]

\[u_{ix}(x,t) = \frac{u(x+h,t) - 2u(x,t) + u(x-h,t)}{h^2} + O(h^2)\]

Where the grid points are:

\[x_{i+1} = x_i + h, \ x_{i-k} = x_i - h, \ t_{j+1} = t_j + k, \ t_{j-1} = t_j - k\]

Neglecting the terms \(O(k)\) and \(O(h^2)\), and use approximation \(u_{i,j}\) for \(u(x_i, t_j)\) in equations (8) and (9), which are in turn substituted in equation (4), we get

\[u_{i,j+1} - u_{i,j} = \frac{u_{i+1,j} - 2u_{i,j} + u_{i-1,j}}{h^2} = \beta u_{i,j}(1-u_{i,j})(u_{i,j} - a)\]

From equation (10), we have

\[u_{i,j+1} - u_{i,j} = r(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + k\beta u_{i,j} (1-u_{i,j})(u_{i,j} - a)\]

Where \(r = k/h^2\)
After some mathematical manipulation, we obtain
\[ u_{i,j+1} = r(u_{i-1,j} + u_{i+1,j}) + (1 - 2r - k\beta)u_{i,j} + k\beta(u_{i,j})^2 (1 + a - u_{i,j}) \] (12)

Equation (12) represents the explicit finite difference formula for equation (4). Equation (12) is employed to create \((j+1)h\) row across the grid, assuming that approximations in the \(j\)th row are known. Notice that this formula explicitly gives the value \(u_{i,j+1}\) in terms of \(u_{i-1,j}, u_{i,j}, \) and \(u_{i+1,j}\).

4. Stability Analysis of the Explicit Scheme Using Fourier (von Neumann) Method

The basic idea of this method is to replace the solution of the finite difference method \(u_{n,m}\) at time \(t\) by \(\psi(t)e^{j\omega t}\), where \(i = \sqrt{-1}, \gamma > 0\) [16].

To apply von Neumann method to equation (4), we resort to the linearized stability analysis [7], we have
\[
\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} - \alpha \beta u
\] (13)

The finite difference explicit formula for (13) is:
\[
\frac{u_{n+1,m} - u_{n,m}}{\Delta t} = \frac{u_{n+1,m} - 2u_{n,m} + u_{n-1,m}}{(\Delta x)^2} - \alpha \beta u_{n,m}
\] (14)

Substituting \(u_{n,m} = \psi(t)e^{j\omega t}\) in (14), we have
\[
\frac{\psi(t + \Delta t)e^{j\omega t} - \psi(t)e^{j\omega t}}{\Delta t} = \frac{\psi(t)e^{j(\omega(t + \Delta t))} - 2\psi(t)e^{j\omega t} + \psi(t)e^{j(\omega(t - \Delta t))}}{(\Delta t)^2} - \alpha \beta \psi(t)e^{j\omega t} \Rightarrow
\]
\[
\left[ \frac{\psi(t + \Delta t) - \psi(t)}{\Delta t} \right]e^{j\omega t} = \frac{\psi(t)}{(\Delta t)^2} \left[ e^{j\omega \Delta t} + e^{-j\omega \Delta t} - 2 \right] - \alpha \beta \psi(t)e^{j\omega t} \Rightarrow
\]
\[
\psi(t + \Delta t) - \psi(t) = r\psi(t) \left[ e^{j\omega \Delta t} + e^{-j\omega \Delta t} - 2 \right] - \alpha \beta \Delta t \psi(t)
\]

Where \(r = k/\Delta t^2\)
\[
\psi(t + \Delta t) - \psi(t) = r\psi(t)\left[\cos \gamma \Delta x + i \sin \gamma \Delta x + \cos \gamma \Delta x - i \sin \gamma \Delta x - 2\right] - a\beta \Delta t \psi(t)
\]
\[
= r\psi(t)\left[2\cos \gamma \Delta x - 2\right] - a\beta \Delta t \psi(t)
\]
\[
= 2r\psi(t)\left[\cos \gamma \Delta x - 1\right] - a\beta \Delta t \psi(t)
\]
\[
= -2r\psi(t)\left[1 - \cos \gamma \Delta x\right] - a\beta \Delta t \psi(t)
\]
\[
= -2r\psi(t)\left[1 - (1 - 2\sin^2(\gamma \Delta x / 2))\right] - a\beta \Delta t \psi(t)
\]
\[
= -4r\psi(t)\sin^2(\gamma \Delta x / 2) - a\beta \Delta t \psi(t) \Rightarrow
\]
\[
\psi(t + \Delta t) = \psi(t) - 4r\psi(t)\sin^2(\gamma \Delta x / 2) - a\beta \Delta t \psi(t)
\]
\[
= [1 - 4r\sin^2(\gamma \Delta x / 2) - a\beta \Delta t] \psi(t) \Rightarrow
\]
\[
\psi(t + \Delta t) / \psi(t) = 1 - 4r\sin^2(\gamma \Delta x / 2) - a\beta \Delta t = \xi
\]

Where \( \xi \) can be visualized as the amplification factor and we get
\[
\psi(t + \Delta t) / \psi(t) = \xi
\]  \hspace{1cm} (15)

As we advance the solution from a particular plane \( \psi(t) \) to the next plane \( \psi(t + \Delta t) \), \( |\psi(t + \Delta t) - \psi(t)| \) must start decreasing or alternatively \( \psi(t) \) must be bounded function, i.e. \( \psi(t) \) should not tend infinity for large \( t \).

From equation (15), for boundedness of (15), we need
\[
|\psi(t + 1) / \psi(t)| \leq 1 \Rightarrow
\]
\[
|\xi| \leq 1 \Rightarrow
\]
\[
|1 - 4r\sin^2(\gamma \Delta x / 2) - a\beta \Delta t| \leq 1
\]  \hspace{1cm} (16)

In the above inequality, the right-side inequality is:
\[
1 - 4r\sin^2(\gamma \Delta x / 2) - a\beta \Delta t \leq 1
\]
Implies \( r > 0 \) and this is always true.

Hence, in order that (16) is to be satisfied, we need
\[
-1 \leq 1 - 4r\sin^2(\gamma \Delta x / 2) - a\beta \Delta t \Rightarrow
\]
\[
-2 \leq 4r\sin^2(\gamma \Delta x / 2) - a\beta \Delta t \Rightarrow
\]
\[
2 \geq 4r\sin^2(\gamma \Delta x / 2) + a\beta \Delta t \Rightarrow
\]
\[
\frac{1}{2} - \frac{a\beta \Delta t}{4} \geq r\sin^2(\gamma \Delta x / 2)
\]

For some \( \beta \), \( \sin^2(\gamma \Delta x / 2) \) is unity and hence the above condition reduces to
\[
r \leq \frac{2 - \alpha \beta \Delta t}{4}
\]  
(17)

Since \( r = \Delta t / (\Delta x)^2 \), from inequality (17), we have

\[
\Delta t \leq \frac{2(\Delta x)^2}{4 + \alpha \beta (\Delta x)^2}
\]  
(18)

This precisely the conditions imposed on the explicit scheme to be stable.

5. Derivation of the Crank-Nicholson Scheme Formula of Huxley Equation

The is diffusion term \( u_{xx} \) in this method is represented by central differences, with their values at the current and previous time steps averaged [17]:

\[
u_{xx} = \frac{1}{2} \left( \frac{u(x-h,t+k) - 2u(x,t+k) + u(x+h,t+k) + u(x-h,t) - 2u(x,t) + u(x+h,t)}{h^2} \right)
\]  
(19)

By using the approximation \( u_{ij} \) for \( u(x_j,t_i) \) in equations (19) and (20), which are in turn substituted into equation (4), we have

\[
u_{i+1,j} - u_{i,j} - \frac{u_{i+1,j+1} + u_{i-1,j+1}}{2} - \frac{u_{i+1,j-1} + u_{i-1,j-1}}{2} = \beta a_i (1 - u_{i,j}) (u_{i,j} - a)
\]  
(21)

From (21), we get

\[
2u_{i,j+1} - 2u_{i,j} - r(u_{i+1,j+1} - 2u_{i,j+1} + u_{i-1,j+1}) = r(u_{i+1,j} - 2u_{i,j} + u_{i-1,j}) + 2k\beta (u_{i,j} - (u_{i,j})^3) (u_{i,j} - a)
\]

\[
r = \frac{k}{h^2}
\]

After some mathematical manipulation, we get

\[
-r(u_{i-1,j+1} + u_{i+1,j+1}) + (2 + 2r)u_{i,j+1} = r(u_{i-1,j} + u_{i+1,j}) + (2 - 2r - 2ak\beta)u_{i,j} + 2k\beta (u_{i,j})^3 (1 + a - u_{i,j}), \quad i = 2, 3, 4, ..., n-1
\]  
(22)

Equation (22) represents the Crank-Nicholson formula for equation (4).

The terms on the right-hand side of equation (22) are all known. Hence, the equations in (22) form a tridiagonal linear algebraic system \( AX = B \).

The boundary conditions are used in the first and last equations only i.e. \( u_{1,j} = u_{1,j+1} = b \), and \( u_{n,j} = u_{n,j+1} = b \), \( \forall j \).

91
Equations in (22) are especially pleasing to view in their tridiagonal matrix form $AX = B$, where $A$ is the coefficient matrix, $X$ is the unknown vector and $B$ is the known vector as shown below:

$$
\begin{bmatrix}
2 + 2r & -r & \\
-r & 2 + 2r & -r \\
-r & 2 + 2r & -r \\
\end{bmatrix}
\begin{bmatrix}
u_{2,j+1} \\
u_{3,j+1} \\
\vdots \\
u_{p,j+1} \\
u_{p-2,j+1} \\
u_{n-1,j+1} \\
u_{n,j+1}
\end{bmatrix} = 
\begin{bmatrix}
2r + (2 - 2r - 2a\beta k)u_{2,j} + 2\beta k(u_{2,j}^2) + ru_{3,j} \\
r(u_{2,j} + u_{3,j}) + (2 - 2r - 2a\beta k)u_{3,j} + 2\beta k(u_{3,j}^2) + (1 + a - u_{3,j}) \\
\vdots \\
r(u_{p-1,j} + u_{p,j}) + (2 - 2r - 2a\beta k)u_{p,j} + 2\beta k(u_{p,j}^2) + (1 + a - u_{p,j}) \\
r(u_{n-2,j} + u_{n-1,j}) + (2 - 2r - 2a\beta k)u_{n-1,j} + 2\beta k(u_{n-1,j}^2) + (1 + a - u_{n-2,j}) \\
r_{n-2,j} + (2 - 2r - 2a\beta k)u_{n-1,j} + 2rb
\end{bmatrix}
$$

When the Crank-Nicholson scheme is implemented with a computer, the linear system $AX = B$ can be solved by either direct means or by iteration. In this paper, the Gaussian elimination method (direct method) has been used to solve the algebraic system $AX = B$.

The finite difference Crank-Nicholson formula for (13) is:

$$
\frac{u_{n,m+1} - u_{n,m}}{\Delta t} = \frac{u_{n+1,m+1} - 2u_{n,m+1} + u_{n-1,m+1}}{2(\Delta x)^2} + \frac{u_{n+1,m} - 2u_{n,m} + u_{n-1,m}}{2(\Delta x)^2} - a\beta \Delta t_k u_{n,m}
$$

Substituting $u_{n,m} = \psi(t)e^{j\pi}$ in equation (23), we have

92
\[
\psi(t + \Delta t)e^{i\phi} - \psi(t)e^{i\phi} = \frac{\psi(t + \Delta t)e^{i\phi(x+\Delta x)} - 2\psi(t + \Delta t)e^{i\phi} + \psi(t)e^{i\phi(x-\Delta x)}}{2(\Delta x)^2} + a\beta \psi(t)e^{i\phi}
\]
\[
\psi(t)e^{i\phi(x+\Delta x)} - 2\psi(t)e^{i\phi} + \psi(t)e^{i\phi(x-\Delta x)} = \frac{a\beta \psi(t)e^{i\phi}}{2(\Delta x)^2} \Rightarrow
\]
\[
\left[ \begin{array}{c} \psi(t + \Delta t) - \psi(t) \\ \psi(t + \Delta t) - \psi(t) \end{array} \right] e^{i\phi} = \frac{\psi(t + \Delta t)e^{i\phi(x+\Delta x)} + \psi(t)e^{i\phi(x-\Delta x)}}{2(\Delta x)^2} \left[ e^{i\phi(x+\Delta x)} + e^{i\phi(x-\Delta x)} - 2 \right] e^{i\phi} \Rightarrow
\]
\[
a\beta \psi(t)e^{i\phi} \Rightarrow
\]
\[
\psi(t + \Delta t) - \psi(t) = \frac{r}{2} \left[ e^{i\phi(x+\Delta x)} + e^{i\phi(x-\Delta x)} - 2 \right] + \frac{r}{2} \left[ e^{i\phi(x+\Delta x)} + e^{i\phi(x-\Delta x)} - 2 \right] - a\beta \Delta t \psi(t)
\]
Where \( r = k / h^2 \)
\[
\psi(t + \Delta t) - \psi(t) = \frac{r}{2} \left[ \cos \gamma \Delta x + i \sin \gamma \Delta x + \cos \gamma \Delta x - i \sin \gamma \Delta x - 2 \right] - a\beta \Delta t \psi(t)
\]
\[
= \frac{r}{2} \left[ 2 \cos \gamma \Delta x - 2 \right] + \frac{r}{2} \left[ 2 \cos \gamma \Delta x - 2 \right] - a\beta \Delta t \psi(t)
\]
\[
= \frac{r}{2} \psi(t + \Delta t) \left[ \cos \gamma \Delta x - 1 \right] + \frac{r}{2} \psi(t) \left[ \cos \gamma \Delta x - 1 \right] - a\beta \Delta t \psi(t)
\]
\[
= \frac{r}{2} \psi(t + \Delta t) \left[ 1 - \cos \gamma \Delta x \right] - \frac{r}{2} \psi(t) \left[ 1 - \cos \gamma \Delta x \right] - a\beta \Delta t \psi(t)
\]
\[
= \frac{r}{2} \psi(t + \Delta t) \left[ 1 - \cos \gamma \Delta x \right] - \frac{r}{2} \psi(t) \left[ 1 - \cos \gamma \Delta x \right] - a\beta \Delta t \psi(t)
\]
\[
= \frac{r}{2} \psi(t + \Delta t) \sin^2 \left( \frac{\gamma \Delta x}{2} \right) - \frac{r}{2} \psi(t) \sin^2 \left( \frac{\gamma \Delta x}{2} \right) - a\beta \Delta t \psi(t) \Rightarrow
\]
\[
\psi(t + \Delta t) \sin^2 \left( \frac{\gamma \Delta x}{2} \right) = \psi(t) \sin^2 \left( \frac{\gamma \Delta x}{2} \right) - a\beta \Delta t \psi(t) \Rightarrow
\]
\[
(1 + 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right)) \psi(t + \Delta t) = (1 - 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right)) - a\beta \Delta t \psi(t) \Rightarrow
\]
\[
\psi(t + \Delta t) \sin^2 \left( \frac{\gamma \Delta x}{2} \right) = \psi(t) \sin^2 \left( \frac{\gamma \Delta x}{2} \right) - a\beta \Delta t \psi(t) \Rightarrow
\]
\[
\psi(t + \Delta t) \sin^2 \left( \frac{\gamma \Delta x}{2} \right) = \frac{1 - 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right) - a\beta \Delta t}{1 + 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right)} \Rightarrow
\]
\[
\psi(t + \Delta t) = \frac{1 - 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right) + a\beta \Delta t}{1 + 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right)} \Rightarrow \psi(t + \Delta t) = \xi \Rightarrow \psi(t + \Delta t) = \psi(t) = \xi
\]
For stability, we need
\[
|\psi(t + \Delta t) / \psi(t)| \leq 1 \Rightarrow
\]
\[
|\xi| \leq 1 \Rightarrow \left| \frac{1 - 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right) + a\beta \Delta t}{1 + 2r \sin^2 \left( \frac{\gamma \Delta x}{2} \right)} \right| \leq 1 , \forall r , a , \beta , \Delta t
\]
Hence, the Crank-Nicholson scheme is unconditionally stable.

7. Conclusions

We concluded from the comparison between the two schemes that the explicit scheme is easier and has faster convergence than the Crank-
Nicholson scheme which is more accurate than the explicit scheme and the results of this paper are affirming the analytical results which obtained by Manoranjan et al [12] as shown below:

(1) If \( b = 0 \) then \( u(x, t) \rightarrow 0 \) as \( t \rightarrow \infty \) if \( L < \pi / (1 - a) \)

(2) If \( b = a \) then \( u(x, t) \rightarrow a \) as \( t \rightarrow \infty \) if \( L < \pi \)

(3) If \( b = 1 \) then \( u(x, t) \rightarrow 1 \) as \( t \rightarrow \infty \) if \( L < \pi / a \)

as shown in figure (1) and table (1). In addition, from stability analysis, we concluded that the explicit scheme is conditionally stable if

\[
r \leq \frac{2 - ab\Delta t}{4}, \quad \Delta t \leq \frac{2(\Delta x)^2}{4 - ab(\Delta x)^2}
\]

while the Crank-Nicholson scheme is unconditionally stable.

Figure (1)

Figure (1) Explains the solution of the Huxley equation by the use of Crank-Nicholson scheme for various values of \( H \) at \( a = b = 0.8 \).

The figure shows that the solution of the problem converges to the steady state solution \( u = a = 0.8 \) as \( t \) gets large at specific boundary condition \( b = 0.8 \).
Table (1) shows the solution of Huxley equation by the use of Crank-Nicholson scheme and explicit scheme for some values of a, b, and H.

The table above explains that the solution of the two schemes converges to the steady state solution $u = a = 0.25$ and the number of steps which are needed to reach the solution $u = a = 0.25$ in the explicit scheme is less than the number of steps in the Crank-Nicholson scheme at specific boundary condition $b = 0.25$ and $H = 0.1, 0.3$.
